This invention relates to a control apparatus for controlling a machine such as a press. There has been known in the art a control apparatus which detects a workpiece whose size or shape changes due to a change in a positional relation between the workpiece and a workpiece supporter in a case where a molding apparatus is controlled by a numerical control (NC) apparatus to machine a mold to thereby produce a molded product. This control apparatus is disclosed in, for example, U.S. Pat. No. 4,509,543. When a molded product is produced by the molding apparatus in the above-mentioned control apparatus, the workpiece supporter supporting the workpiece is positioned to a work station and then a mechanical arm of the molding apparatus is operated to carry out a first punch operation, a second punch operation or a third punch operation. For this reason, in the case where the workpiece supporter is not positioned at the work station in which the first punch operation is to be carried out, it is necessary to make a replacement to the workpiece supporter before the first punch operation is carried out. Further, it is also necessary to carry out an operation for putting the workpiece supporter into a standby state. In the case where the workpiece supporter is positioned at the work station after the first punch operation is finished, a time is necessary to carry out an operation for pushing the workpiece supporter into the work station after the first punch operation is finished. Accordingly, the molding operation is considerably delayed because of the above-mentioned replacement and the above-mentioned operation for pushing the workpiece supporter into the work station. In addition, since the molding apparatus is equipped with an exclusive
